

ATLAS PEERING

Peering capacity at public Internet exchanges

What reported port capacity reveals about
the choices of 10 hyperconnected CDN,
cloud and content networks.

Gael Hernandez
EPF 2026 Paris

Pe (Gbps)

<https://www.atlaspeering.com/epf2026.pdf>

Study scope and analytical lens

- The study aggregates public-IXP port capacity for the ten most-IXP interconnected networks (*): Akamai, Meta, Amazon, Hurricane Electric, Cloudflare, Fastly, Microsoft, Google, Netskope and ACE CDN. Data was retrieved on August 15th 2026.
- IXPs are ranked by the sum of reported port capacity (netixlan objects) deployed by these networks, allowing individual and collective deployment choices to be compared.
- The analysis treats public peering capacity as a lens into physical infrastructure, regional traffic distribution and interconnection priorities—not as a direct traffic measurement.

* The original study published in RIPE Labs included Netflix and ByteDance instead of Netskope and ACE CDN.

Method limitations and confidence

- Exchange presence records may be incorrect, and reported port capacity may be incomplete or out of date.
 - However, most networks (*) in the study rely heavily on Peering DB automation for peering requests/approvals, which increases confidence in the consistency of their records.
- Reported capacity should therefore be interpreted as a strategic deployment signal, with appropriate caution around precision and freshness.

* Cloudflare, Meta, Google, Amazon require an up-to-date PeeringDB network page as per their peering policy.

At a glance: capacity leaders

- Akamai leads the benchmark with 81.3 Tbps of deployed public-peering capacity across 250 exchanges, consistent with a long-standing strategy of distributing content close to end users.
- Meta follows with 76 Tbps despite appearing at fewer exchanges, indicating very high-capacity deployments concentrated in important metros.
- Amazon ranks third with 53.4 Tbps, reflecting the growing role of AWS and cloud-driven traffic at public exchanges.

ASN	Name	IX count	Port count	Port Capacity (Tbps) ▼
20940	Akamai	250	383	81.3
32934	Meta	209	440	76.0
16509	Amazon	167	339	53.4
6939	Hurricane	335	336	53.2
13335	Cloudflare	357	418	51.7
54113	Fastly	152	203	48.3
8075	Microsoft	207	371	40.1
15169	Google	176	317	29.9
139341	ACE CDN	123	168	22.44
55256	Netskope	142	203	17.2

At a glance: footprint leaders

- Cloudflare has the broadest presence in the dataset, participating at 357 exchanges worldwide.
- Hurricane Electric—the only non-CDN network in the benchmark—has the second-largest footprint, with connectivity to 335 IXPs.
- Akamai, Microsoft and Meta also maintain substantial global public-peering footprints (more than 200 exchanges).
- Fastly, Netskope and ACE CDN close the ranking.

Map view

Peering Capacity (Gbps)

Global observations: top leading exchanges

- IX.br São Paulo, Equinix Singapore and DE-CIX Frankfurt are the top 3
 - They are also the three largest exchanges by traffic.
- 3 Brazilian exchanges (Sao Paulo, Rio and Fortaleza) appear in the global top seven.
- IXPs in every continent except Africa (coming on #14).
- 9 out of 10 are community exchanges

Rank	IX Name	ASNs	Peak Traffic Tbps	Average Traffic Tbps	Capacity Tbps
1	IX.br Sao Paulo	1,856	33.12	20.21	20.20
2	Equinix Singapore	466	20.1	14.3	11.10
3	DE-CIX Frankfurt	1,015	18.66	13.38	10.60
4	IX.br Fortaleza	601	7.08	3.67	7.70
5	NL-ix	533	13.36	7.01	7.40
6	BBIX Tokyo	355	7.76	5.42	7.00
7	IX.br Rio de Janeiro	523	5.52	2.84	7.00
8	AMS-IX	861	13.6	9.54	6.50
9	CIX-ATL	117	3.04	1.92	5.70
10	SIX Seattle	368	2.8	2.18	5.60

Global observations: global hubs and regional distribution

- Geographically, Asia-Pacific contributes 11 exchanges, North America 8, Europe 6, South America 4 and Africa 1.
- The top thirty exchange points function as a set of global and regional anchor points for content distribution. Nearly every network in the study appears at nearly every exchange in this group. Exceptions are limited and specific.
- Commercial colocation-led exchanges are relatively scarce in the top 30, although Equinix holds five places in the global top 20.

Europe: the FLAP hierarchy is changing

- European interconnection discussions have historically centered on Frankfurt, London, Amsterdam and Paris (FLAP).
- DE-CIX, NL-IX, AMS-IX and LINX are the top 4 IXPs.
- Paris does not appear in this dataset; MIX-IT in Milan and Peering.cz in Prague occupy the last places instead.
- The ranking challenges the assumption that the familiar FLAP hierarchy fully describes current public-peering importance.
- Distributed exchanges appear in the rankings now.

Europe: distributed IX fabrics and newcomers

- NL-IX operates a highly distributed model spanning more than eight countries, with over 525 participants across 83 facilities in 12 European cities.
 - Its position suggests that distributed exchange architectures can complement—or partly substitute for—the traditional single-metro exchange model.
- MIX-IT appears forth in the global ranking, reinforcing Milan's position as a Southern European interconnection hub.
 - MIX-IT is also unusual in operating its own data-centre facility, MIX DC Caldera.
- Peering.cz is the final European exchange in the global ranking, also with a distributed fabric across Prague, Bratislava, Vienna and Frankfurt.

South America: Brazil dominates the ranking

- South America's leading exchanges are overwhelmingly Brazilian: IX.br Sao Paulo, IX.br Fortaleza and IX.br Rio de Janeiro.
- PIT Chile in Santiago is the only non-Brazilian exchange from the region in the global top 30.
- Brazil demonstrates how a coordinated national exchange strategy can materially affect traffic localisation and content-distribution economics.
- The scale of IX.br (39 IXPs) creates a domestic public-peering environment that is difficult for global content networks to ignore.

South America: Meta's large peering capacity

- Meta deploys 14 Tbps in Brazil: 7.2 Tbps at IX.br São Paulo, 4.8 Tbps at IX.br Fortaleza and 2 Tbps at IX.br Rio de Janeiro. Second to Meta is Akamai with only 5.8 Tbps – just under a third – and Fastly with 4.
- These massive deployments suggest that public peering is a principal delivery mechanism for Meta in Brazil, potentially reflecting the country's well-known logistics and import complexity.
- Fortaleza is additionally important as a submarine-cable landing hub linking South America with North America, Europe and increasingly Africa.

Rank	IX Name	City	Country Code	Continent	Meta AS32934

Asia-Pacific: the strongest top-30 representation

- Asia-Pacific contains more exchanges in the global top 30 than any other region.
- The leading platforms are Equinix Singapore and BBIX Tokyo, followed by JPIX Tokyo, ExtremelX Mumbai, Equinix Hong Kong and SGIX.
- The ranking confirms the continued importance of Singapore (3x), Tokyo (3x) and Hong Kong (2x) as regional interconnection capitals, and adds Mumbai and Delhi to the map.
- Exchanges in Indonesia and Australia are missing from the top 30 ranking.

Asia-Pacific: Multiple fabric, rises and absents

- Japan sustains multiple peering fabrics within the same metro areas (Tokyo and Osaka), reflecting both the scale and competitive diversity of its Internet ecosystem.
 - JPNAP, JPIX and BBIX are three distinct families
- Extreme-IX Mumbai and Extreme-IX Delhi are the most prominent platforms for CDN deployment in India within the dataset.
 - Their position aligns with growth in Internet usage, video consumption, mobile broadband and hyperscale infrastructure investment in a market of more than 1.4 billion people.
- Australian exchanges do not appear in the top 30, potentially because of population scale and alternative architectures such as deep caching.
 - Australia's ISP market is concentrated around Telstra, Vocus, Optus and TPG, which may favour different delivery and interconnection choices.
- Indonesia also missing despite two very active a large exchanges JKT-IX and IIX-Jakarta on positions #40 and #42

North America: public exchanges play a different role

- CIX ATL in Atlanta is the highest-ranked North American exchange but is only ninth globally.
- Followed by SIX Seattle, Equinix Chicago, Equinix Dallas, Equinix Ashburn, FL-IX, Tor-IX and DE-CIX New York.
- North America's historical preference for private interconnection rather than concentration at large public exchanges is notorious in the industry.
- North America nevertheless remains strongly represented overall, with six exchanges in the global top 20.

North America: community-led exchanges and Canada

- SIX Seattle, CIX Atlanta, FL-IX Miami and TorIX demonstrate that community-driven and carrier-neutral exchange models remain important in a highly commercialised market.
- DE-CIX New York present in the ranking ahead of other “domestic” options such as NYIIX or Equinix New York.
- Canada places just one exchange in the global top 30 - TorIX is ranked 26th.
 - Mostly likely due to Canada’s smaller domestic Internet population and dependence on US interconnection ecosystems.

Africa: Johannesburg is the continental anchor

- NAPAfrica Johannesburg is the only African exchange in the global top 30 and ranks 14th worldwide.
- Its position within a global ranking demonstrates Johannesburg's role as Africa's principal digital and interconnection hub.
- The next African platform is IXPN Lagos at 47th, illustrating the broader gap in interconnection density between Africa and other regions.

Key takeaways: public peering remains strategic

- Public peering remains strategically important even in the hyperscale era.
- Major CDN, cloud and content networks continue to invest heavily in public exchanges even as private backbone infrastructure expands.
- IXPs remain valuable for efficient access to eyeball networks, lower-latency paths, regional traffic localisation, cache efficiency and resilience.
- Public interconnection should therefore be understood as complementary components of hyperscale edge architecture.
- The overall pattern shows that public peering remains embedded in hyperscale Internet architecture even where extensive private backbones exist.

Key takeaways: geography and demographics still matter

- The largest exchanges tend to sit in metros combining dense fibre ecosystems, hyperscale data centres, submarine-cable connectivity and large Internet-user populations.
- Public peering is no longer dominated exclusively by North American and European exchanges. Brazil, Singapore, Tokyo, Mumbai and Johannesburg now operate as important regional hubs in the global interconnection fabric.
- In Europe, distributed (multi-city) exchanges are complementary to single-metro exchange points.
- Capacity allocation across these hubs provides a useful signal of how major networks perceive traffic gravity, reach and operational value.

Call for action to support PeeringDB

- Contribute accurate, up-to-date network, facility, and exchange data to strengthen the resource everyone relies on.
- Volunteer your expertise to help improve PeeringDB's governance, tools, documentation, and community support.
- Become a financial sponsor so PeeringDB can maintain resilient infrastructure and develop new capabilities.
- Integrate PeeringDB into your workflows—and share feedback to make its automation and planning data even more useful.
- Champion PeeringDB across the interconnection community by encouraging partners and peers to contribute, volunteer, and sponsor.
